Table Memory

A source-linked family cookbook for UGREEN AI NAS · Hackathon 2026 · Entrant: Iyanda Abdulqodir Adedolapo

1. Skill

Table Memory turns family recipe cards, scans, screenshots and notes on a UGREEN AI NAS into a source-linked cookbook.

2. User and problem

Families inheriting recipe boxes: handwritten cards, phone screenshots, PDFs and voice notes. Generic scanning can flatten family notes and provenance; some families prefer not to upload private memories.

3. Solution

A NAS Skill inventories one dish or 12 files, recovers recipes with OCR and extraction, transcribes approved audio, and presents a review table. It saves a cookbook, optional shopping list and approved correction record. A later session reuses the correction only when its source fingerprint and field match, so a family explains a detail once without merging versions. Originals stay untouched.

4. User flow

Choose a recipe folder; inventory and fingerprint files; recover recipes; attach approved voice notes; review missing or ambiguous fields; approve the cookbook; optionally scale and build a shopping list.

5. Differentiation

It is not a recipe generator. A family may have three jollof versions; Table Memory keeps all three as branches, shows what changed, and cites every ingredient and step to its source. It refuses to guess a quantity, temperature, time or unit.

6. NAS features

File listing, metadata and SHA-256 fingerprints; photo OCR and layout reading; document extraction and page coverage; audio transcription; knowledge save for the cookbook, shopping list and correction record.

7. Technical approach

A Markdown Uliya Skill delegates to the file, document, photo and knowledge experts. It uses catalogued capabilities, asks before audio, and requires approval before writing. Processing location will be verified on the NAS. Handles completed, failed, cancelled and waiting states. The submitted Skill needs no external API or credential.

8. Status

Built: Skill and five references; checker static-pass, zero errors/warnings. Tested locally: a synthetic worked example produced a source-linked cookbook and correction record; it is not a UGOS or NAS run. NAS execution, handwriting and read-back remain finalist tests.

9. Validation

Core one: two synthetic recipe versions with one blurred quantity; expect separate branches, source evidence and the unclear value unresolved. Core two: approve a clarification, save/read back, then reopen in a fresh session; expect reuse only for the matching source, branch and locator, with no repeat question and no leak into the other version. Edge case: change the source after approval; expect a fingerprint mismatch, no automatic reuse and review. Voice, scaling and misleading-scan cases remain in the test plan.

10. Limits

Handwriting and cropped text can reduce accuracy; mixed units and whole eggs cannot always be scaled safely; transcription may miss speech or speaker changes. Models vary by device. The Skill is a personal archive, not nutritional, medical or food-safety advice. It depends on the UGREEN catalog and the assigned NAS.

Third-party components: none bundled. Development used Uliya 0.7.3 and catalog 2.0.0; ChatGPT-assisted drafting and checking; ElevenLabs TTS and hosted Scribe v2 were used for rehearsal only.
